# Package 'ODRF'

January 2, 2023

```
Type Package
Title Oblique Decision Random Forest for Classification and Regression
Version 1.0-1
Date 2022-09-21
Author Yu Liu liuyuchina123@gmail.com>, Yingcun Xia <staxyc@nus.edu.sg>
Maintainer Yu Liu liuyuchina123@gmail.com>
Description The oblique decision tree (ODT) uses linear combinations of predictors as partition-
      ing variables in a decision tree. Oblique Decision Random Forest (ODRF) is an ensem-
     ble of multiple ODTs generated by feature bagging. Both can be used for classification and re-
     gression as supplements to the classical CART and Random Forest respectively.

## Description

To make ODT object to objects of class party.

best.cut.node 3

#### Usage

```
## S3 method for class 'ODT'
as.party(obj, data, ...)
```

#### **Arguments**

obj An object of class ODT.

data Training data of class data.frame is used to convert the object of class ODRF.

and data must be the training data data in ODT.

... Arguments to be passed to methods

#### References

Lee, EK(2017) PPtreeViz: An R Package for Visualizing Projection Pursuit Classification Trees, Journal of Statistical Software <doi:10.18637/jss.v083.i08>

## See Also

```
ODT party
```

## **Examples**

```
data(iris)
tree <- ODT(Species ~ ., data = iris)
tree
plot(tree)
party.tree <- as.party(tree, data = iris)
party.tree
plot(party.tree)</pre>
```

best.cut.node

find best split variable and node.

## **Description**

A function to select the splitting variables and nodes using one of three criteria.

#### Usage

```
best.cut.node(
   X,
   y,
   type = "i-classification",
   weights = 1,
   MinLeaf = ifelse(type == "regression", 5, 1),
   numLabels = ifelse(type == "regression", 0, length(unique(y)))
)
```

4 body\_fat

## **Arguments**

Χ	An n by d numeric matrix (preferable) or data frame.
у	A response vector of length n.
type	One of three criteria, 'i-classification': information gain (classification, default), 'g-classification': gini impurity index (classification) or 'regression': mean square error (regression).
weights	A vector of values which weigh the samples when considering a split.
MinLeaf	The minimum amount of samples in a leaf.

numLabels The number of categories.

## Value

A list which contains:

- BestCutVar: The best split variable.
- BestCutVal: The best split point for the best split variable.
- BestIndex: Each variable corresponds to the min gini impurity index(method='g-classification'), the max information gain(method='i-classification') or the min squared error(method='regression').

## **Examples**

```
### Find the best split variable ###
data(iris)
X <- as.matrix(iris[, 1:4])
y <- iris[[5]]
bestcut <- best.cut.node(X, y, type = "i-classification")
print(bestcut)</pre>
```

body\_fat

Body Fat Prediction Dataset

## **Description**

Lists estimates of the percentage of body fat determined by underwater weighing and various body circumference measurements for 252 men. Accurate measurement of body fat is inconvenient/costly and it is desirable to have easy methods of estimating body fat that are not inconvenient/costly.

## **Format**

A data frame with 252 rows and 15 covariate variables and 1 response variable

body\_fat 5

#### **Details**

The variables listed below, from left to right, are:

- · Density determined from underwater weighing
- Age (years)
- Weight (lbs)
- Height (inches)
- Neck circumference (cm)
- Chest circumference (cm)
- Abdomen 2 circumference (cm)
- Hip circumference (cm)
- Thigh circumference (cm)
- Knee circumference (cm)
- Ankle circumference (cm)
- Biceps (extended) circumference (cm)
- Forearm circumference (cm)
- Wrist circumference (cm)

breast\_cancer seeds

```
data(body_fat)
set.seed(221212)
train <- sample(1:252, 100)
train_data <- data.frame(body_fat[train, ])
test_data <- data.frame(body_fat[-train, ])

forest <- ODRF(Density ~ ., train_data, type = "regression", parallel = FALSE)
pred <- predict(forest, test_data[, -1])
# estimation error
mean((pred - test_data[, 1])^2)

tree <- ODT(Density ~ ., train_data, type = "regression")
pred <- predict(tree, test_data[, -1])
# estimation error
mean((pred - test_data[, 1])^2)</pre>
```

6 breast\_cancer

breast\_cancer

Breast Cancer Dataset

## **Description**

Breast cancer is the most common cancer amongst women in the world. It accounts for 25% of all cancer cases, and affected over 2.1 Million people in 2015 alone. It starts when cells in the breast begin to grow out of control. These cells usually form tumors that can be seen via X-ray or felt as lumps in the breast area. The key challenges against it's detection is how to classify tumors into malignant (cancerous) or benign(non cancerous).

#### **Format**

A data frame with 569 rows and 30 covariate variables and 1 response variable

#### **Details**

The actual linear program used to obtain the separating plane in the 3-dimensional space is that described in:

- ID number
- Diagnosis (M = malignant, B = benign)
- Ten real-valued features are computed for each cell nucleus:
  - radius (mean of distances from center to points on the perimeter)
  - texture (standard deviation of gray-scale values)
  - perimeter
  - area
  - smoothness (local variation in radius lengths)
  - compactness (perimeter^2 / area 1.0)
  - concavity (severity of concave portions of the contour)
  - concave points (number of concave portions of the contour)
  - symmetry
  - fractal dimension ("coastline approximation" 1)

#### **Examples**

```
data(breast_cancer)
set.seed(221212)
train <- sample(1:569, 200)
train_data <- data.frame(breast_cancer[train, -1])
test_data <- data.frame(breast_cancer[-train, -1])

forest <- ODRF(diagnosis ~ ., train_data, type = "i-classification", parallel = FALSE)
pred <- predict(forest, test_data[, -1])
# classification error
(mean(pred != test_data[, 1]))

tree <- ODT(diagnosis ~ ., train_data, type = "i-classification")
pred <- predict(tree, test_data[, -1])
# classification error
(mean(pred != test_data[, 1]))</pre>
```

**ODRF** 

Classification and Regression with Oblique Decision Random Forest

#### **Description**

Classification and regression implemented by the oblique decision random forest. It is an extension of random forest and include random forest as a special case. It usually produces more accurate predictions, but needs a long computation time.

## Usage

```
ODRF(X, ...)
## S3 method for class 'formula'
ODRF(
  formula,
  data = NULL,
  type = "auto",
  NodeRotateFun = "RotMatPPO",
  FunDir = getwd(),
  paramList = NULL,
  ntrees = 100,
  storeOOB = TRUE,
  replacement = TRUE,
  stratify = TRUE,
  num00B = 1/3,
  parallel = TRUE,
  numCores = Inf,
  seed = 220924,
  MaxDepth = Inf,
  numNode = Inf,
  MinLeaf = 5,
  subset = NULL,
  weights = NULL,
```

```
na.action = na.fail,
  catLabel = NULL,
  Xcat = 0,
  Xscale = "Min-max",
  TreeRandRotate = FALSE,
## Default S3 method:
ODRF(
  Χ,
  у,
  type = "auto",
  NodeRotateFun = "RotMatPPO",
  FunDir = getwd(),
  paramList = NULL,
  ntrees = 100,
  storeOOB = TRUE,
  replacement = TRUE,
  stratify = TRUE,
  numOOB = 1/3,
  parallel = TRUE,
  numCores = Inf,
  seed = 220924,
  MaxDepth = Inf,
  numNode = Inf,
  MinLeaf = 5,
  subset = NULL,
  weights = NULL,
  na.action = na.fail,
  catLabel = NULL,
  Xcat = 0,
  Xscale = "Min-max",
  TreeRandRotate = FALSE,
)
```

## **Arguments**

Χ

type

	Optional parameters to be passed to the low level function.
formula	Object of class formula with a response describing the model to fit. If this is a data frame, it is taken as the model frame. (see model.frame)
data	Training data of class data. frame in which to interpret the variables named in the formula. If data is missing it is obtained from the current environment by formula.

An n by d numeric matrix (preferable) or data frame.

The criterion used for splitting the nodes. 'i-classification': information gain and 'g-classification': gini impurity index for classification; 'regression': mean square error for regression. 'auto' (default): If the response in data or y is a factor, 'g-classification' is used, otherwise regression is assumed.

NodeRotateFun Name of the function of class character that implements a linear combination of predictors in the split node. including

• "RotMatPPO": projection pursuit optimization model (PPO), see RotMatPPO (default, model="PPR").

- "RotMatRF": single feature similar to random forest, see RotMatRF.
- "RotMatRand": random rotation, see RotMatRand.
- "RotMatMake": users can define this function, for details see RotMatMake.

FunDir The path to the function of the user-defined NodeRotateFun (default current working directory).

paramList List of parameters used by the functions NodeRotateFun. If left unchanged,

default values will be used, for details see defaults.

The number of trees in the forest (default 100).

store00B If TRUE then the samples omitted during the creation of a tree are stored as part

of the tree (default TRUE).

replacement if TRUE then n samples are chosen, with replacement, from training data (de-

fault TRUE).

ntrees

stratify If TRUE then class sample proportions are maintained during the random sam-

pling. Ignored if replacement = FALSE (default TRUE).

num00B Ratio of 'out-of-bag' (default 1/3).

parallel Parallel computing or not (default TRUE).

numCores Number of cores to be used for parallel computing (default Inf).

seed Random seeds in order to reproduce results.

MaxDepth The maximum depth of the tree (default Inf).

numNode Number of nodes that can be used by the tree (default Inf).

MinLeaf Minimal node size. Default 1 for classification, 5 for regression.

subset An index vector indicating which rows should be used. (NOTE: If given, this

argument must be named.)

weights Vector of non-negative observational weights; fractional weights are allowed

(default NULL).

na.action A function to specify the action to be taken if NAs are found. (NOTE: If given,

this argument must be named.)

catLabel A category labels of class list in predictors. (default NULL, for details see

Examples)

Xcat A class vector is used to indicate which predictor is the categorical variable, the

default Xcat=0 means that no special treatment is given to category variables. When Xcat=NULL, the predictor x that satisfies the condition (length(unique(x))<10)

& (n>20) is judged to be a category variable.

Xscale Predictor standardization methods. "Min-max" (default), "Quantile", "No" de-

note Min-max transformation, Quantile transformation and No transformation

respectively.

TreeRandRotate If or not to randomly rotate the Training data before building the tree (default

FALSE).

y A response vector of length n.

#### Value

An object of class ODRF Containing a list components:

- · call: The original call to ODRF.
- terms: An object of class c("terms", "formula") (see terms.object) summarizing the formula. Used by various methods, but typically not of direct relevance to users.
- ppTrees: Each tree used to build the forest.
  - oobErr: 'out-of-bag' error for tree, misclassification rate (MR) for classification or mean square error (MSE) for regression.
  - oobIndex: Which training data to use as 'out-of-bag'.
  - oobPred: Predicted value for 'out-of-bag'.
  - other: For other tree related values ODT.
- oobErr: 'out-of-bag' error for forest, misclassification rate (MR) for classification or mean square error (MSE) for regression.
- oobConfusionMat: 'out-of-bag' confusion matrix for forest.
- type, Levels and NodeRotateFun are important parameters for building the tree.
- paramList: Parameters in a named list to be used by NodeRotateFun.
- data: The list of data related parameters used to build the forest.
- tree: The list of tree related parameters used to build the tree.
- forest: The list of forest related parameters used to build the forest.

ODRF\_accuracy

accuracy of oblique decision random forest

#### **Description**

Prediction accuracy of ODRF at different tree sizes.

#### Usage

```
ODRF_accuracy(ppForest, data, newdata = NULL)
```

## **Arguments**

ppForest an object of class ODRF, as that created by the function ODRF.

data Training data of class data. frame in ODRF is used to calculate the OOB error.

newdata A data frame or matrix containing new data is used to calculate the test error. If

it is missing, let it be data.

#### Value

OOB error and test error, misclassification rate (MR) for classification or mean square error (MSE) for regression.

ODT 13

Classification and Regression with Oblique Decision Tree

## Description

Classification and regression using an oblique decision tree (ODT) in which each node is split by a linear combination of predictors. Different methods are provided for selecting the linear combinations, while the splitting values are chosen by one of three criteria.

#### Usage

```
ODT(X, ...)
## S3 method for class 'formula'
ODT(
  formula,
  data = NULL,
  type = "auto",
  NodeRotateFun = "RotMatPPO",
  FunDir = getwd(),

  MaxDepth = Inf,
  numNode = Inf,
  MinLeaf = 5,
  Levels = NULL,
  subset = NULL,
  weights = NULL,
  na.action = na.fail,
  catLabel = NULL,
  Xcat = 0,
  Xscale = "Min-max",
  TreeRandRotate = FALSE,
)
## Default S3 method:
ODT(
  Χ,
  у,
  type = "auto",
  NodeRotateFun = "RotMatPPO",
  FunDir = getwd(),
  paramList = NULL,
  MaxDepth = Inf,
  numNode = Inf,
  MinLeaf = 5,
  Levels = NULL,
  subset = NULL,
  weights = NULL,
  na.action = na.fail,
  catLabel = NULL,
```

ODT

ODT ODT

```
Xcat = 0,
Xscale = "Min-max",
TreeRandRotate = FALSE,
...
)
```

## **Arguments**

X An n by d numeric matrix (preferable) or data frame.

... Optional parameters to be passed to the low level function.

formula Object of class formula with a response describing the model to fit. If this is a

data frame, it is taken as the model frame. (see model.frame)

data Training data of class data. frame in which to interpret the variables named in

the formula. If data is missing it is obtained from the current environment by

formula.

type The criterion used for splitting the nodes. 'i-classification': information gain

and 'g-classification': gini impurity index for classification; 'regression': mean square error for regression; 'auto' (default): If the response in data or y is a

factor, 'g-classification' is used, otherwise regression is assumed.

NodeRotateFun Name of the function of class character that implements a linear combination

of predictors in the split node. including

 "RotMatPPO": projection pursuit optimization model (PPO), see RotMatPPO (default, model="PPR").

• "RotMatRF": single feature similar to random forest, see RotMatRF.

• "RotMatRand": random rotation, see RotMatRand.

• "RotMatMake": users can define this function, for details see RotMatMake.

FunDir The path to the function of the user-defined NodeRotateFun (default current

working directory).

paramList List of parameters used by the functions NodeRotateFun. If left unchanged,

default values will be used, for details see defaults.

MaxDepth The maximum depth of the tree (default Inf).

numNode Number of nodes that can be used by the tree (default Inf).

MinLeaf Minimal node size. Default 1 for classification, 5 for regression.

Levels The category label of the response variable when type is not equal to 'regres-

sion'.

subset An index vector indicating which rows should be used. (NOTE: If given, this

argument must be named.)

weights Vector of non-negative observational weights; fractional weights are allowed

(default NULL).

na.action A function to specify the action to be taken if NAs are found. (NOTE: If given,

this argument must be named.)

catLabel A category labels of class list in predictors. (default NULL, for details see

Examples)

Xcat A class vector is used to indicate which predictor is the categorical variable.

The default Xcat=0 means that no special treatment is given to category vari-

ables. When Xcat=NULL, the predictor x that satisfies the condition (length(unique(x))<10)

& (n>20) is judged to be a category variable.

ODT 15

Xscale Predictor standardization methods. "Min-max" (default), "Quantile", "No" denote Min-max transformation, Quantile transformation and No transformation respectively.

TreeRandRotate If or not to randomly rotate the Training data before building the tree (default

FALSE).

y A response vector of length n.

#### Value

An object of class ODT Containing a list components:

- call: The original call to ODT.
- terms: An object of class c("terms", "formula") (see terms.object) summarizing the formula. Used by various methods, but typically not of direct relevance to users.
- projections: Projection direction for each node.
- structure: A set of tree structure data records.
  - nodeRotaMat: Record the split variables (first column), split node serial number (second column) and rotation direction (third column) for each node. (The first column and the third column are 0 means leaf nodes)
  - nodeNumLabel: Record each leaf node's category for classification or predicted value for regression (second column is data size). (Each column is 0 means it is not a leaf node)
  - nodeCutValue: Record the split point of each node. (0 means leaf nodes)
  - nodeCutIndex: Record the index values of the partitioning variables selected based on the partition criterion type.
  - childNode: Record the number of child nodes after each splitting.
  - nodeDepth: Record the depth of the tree where each node is located.
- type, Levels and NodeRotateFun are important parameters for building the tree.
- paramList: Parameters in a named list to be used by NodeRotateFun.
- data: The list of data related parameters used to build the tree.
- tree: The list of tree related parameters used to build the tree.

online

online structure learning for class ODT and ODRF.

## **Description**

ODT and ODRF are constantly updated by multiple batches of data to optimize the model. online is a S3 method for class ODT and ODRF.

## Usage

```
online(obj, ...)
```

## **Arguments**

obj an object of class ODT or ODRF.

... For other parameters related to class obj, see ODT or ODRF.

#### Value

object of class ODT or ODRF.

#### See Also

```
ODT ODRF online.ODT online.ODRF
```

on	П	1	ne	. ()	I)	Кŀ	-

using training data to update an existing ODRF.

## **Description**

Update existing ODRF using batches of data to improve the model.

#### Usage

```
## S3 method for class 'ODRF'
online(obj, X, y, weights = NULL, ...)
```

## **Arguments**

obj	An object of class ODRF.
X	An n by d numeric matrix (preferable) or data frame is used to update the object of class ODRF.
у	A response vector of length n is used to update the object of class ODRF.
weights	Vector of non-negative observational weights; fractional weights are allowed (default NULL).
	optional parameters to be passed to the low level function.

#### Value

The same result as ODRF.

#### See Also

plot.ODRF\_accuracy

plot method for ODRF\_accuracy objects

## Description

Draw the error graph of class ODRF at different tree sizes.

## Usage

```
## S3 method for class 'ODRF_accuracy'
plot(x, lty = 1, digits = NULL, main = NULL, ...)
```

## Arguments

X	Object of class ODRF_accuracy.
lty	A vector of line types, see par.
digits	Integer indicating the number of decimal places (round) or significant digits (signif) to be used.
main	main title of the plot.
	Arguments to be passed to methods.

#### Value

OOB error and test error, misclassification rate (MR) for classification or mean square error (MSE) for regression.

## See Also

```
ODRF ODRF_accuracy

train_data <- data.frame(breast_cancer[train, -1])
test_data <- data.frame(breast_cancer[-train, -1])

forest <- ODRF(diagnosis ~ ., train_data, type = "i-classification", parallel = FALSE)
(error <- ODRF_accuracy(forest, train_data, test_data))
plot(error)</pre>
```

plot.ODT

to plot an oblique decision tree

## **Description**

Draw oblique decision tree with tree structure. It is modified from a function in PPtreeViz library.

## Usage

```
## S3 method for class 'ODT'
plot(x, font.size = 17, width.size = 1, xadj = 0, main = NULL, sub = NULL, ...)
```

#### **Arguments**

x An object of class ODT.
 font.size Font size of plot
 width.size Size of eclipse in each node.
 xadj The size of the left and right movement.
 main main title
 sub title
 ... Arguments to be passed to methods.

22 plot.prune.ODT

plot.prune.ODT	to plot pruned oblique decision tree

## **Description**

Plot the error graph of the pruned oblique decision tree at different split nodes.

## Usage

```
## S3 method for class 'prune.ODT'
plot(x, position = "topleft", digits = NULL, main = NULL, ...)
```

#### **Arguments**

X	An object of class prune. ODT.
position	Position of the curve label.
digits	Integer indicating the number of decimal places (round) or significant digits (signif) to be used.
main	main title
	Arguments to be passed to methods.

## Value

Error of validation data after each pruning, misclassification rate (MR) for classification or mean square error (MSE) for regression.

## See Also

```
ODT prune.ODT
```

```
data(body_fat)
set.seed(221212)

tree <- ODT(Density ~ ., train_data, type = "regression")
prune_tree <- prune(tree, test_data[, -1], test_data[, 1])
# Plot pruned oblique decision tree structure (default)
plot(prune_tree)
# Plot the error graph of the pruned oblique decision tree.
class(prune_tree) <- "prune.ODT"
plot(prune_tree)</pre>
```

plot.VarImp 23

plot.VarImp Variable Importance Plot
--------------------------------------

## Description

Dotchart of variable importance as measured by a Oblique Decision Random Forest.

## Usage

```
## S3 method for class 'VarImp'
plot(x, nvar = 30, digits = NULL, main = NULL, ...)
```

## Arguments

x	An object of class VarImp.
nvar	How many variables to show.
digits	Integer indicating the number of decimal places (round) or significant digits (signif) to be used.
main	plot title.
	Arguments to be passed to methods.

#### Value

A matrix of importance measure, first column for each predictor variable and second column is Increased error. Error is misclassification rate (MR) for classification or mean square error (MSE) for regression.

## See Also

```
ODRF VarImp
```

```
data(breast_cancer)
set.seed(221212)
train <- sample(1:569, 200)

forest <- ODRF(diagnosis ~ ., train_data,
    type = "i-classification", parallel = FALSE
)
(varimp <- VarImp(forest, train_data[, -1], train_data[, 1]))
plot(varimp, digits = 0)</pre>
```

24 plot\_ODT\_depth

plot\_ODT\_depth

plot oblique decision tree depth

## **Description**

Draw the error graph of class ODT at different depths.

#### Usage

```
plot_ODT_depth(
  formula,
  data = NULL,
  newdata = NULL,
  type = "i-classification",
  NodeRotateFun = "RotMatPPO",
  paramList = NULL,
  digits = NULL,
  main = NULL,
  ...
)
```

#### **Arguments**

formula

Object of class formula with a response describing the model to fit. If this is a data frame, it is taken as the model frame. (see model.frame)

data

Training data of class data. frame in ODT is used to calculate the OOB error.

newdata

A data frame or matrix containing new data is used to calculate the test error. If it is missing, let it be data.

type

The criterion used for splitting the nodes. 'i-classification': information gain and 'g-classification': gini impurity index for classification; 'regression': mean square error for regression. 'auto' (default): If the response in data is a factor, 'g-classification' is used, otherwise regression is assumed.

 ${\tt NodeRotateFun}$ 

Name of the function of class character that implements a linear combination of predictors in the split node. including

- "RotMatPPO": projection pursuit optimization model (PPO), see RotMatPPO (default, model="PPR").
- "RotMatRF": single feature similar to random forest, see RotMatRF.
- "RotMatRand": random rotation, see RotMatRand.
- "RotMatMake": Users can define this function, for details see RotMatMake.

paramList

List of parameters used by the functions NodeRotateFun. If left unchanged, default values will be used, for details see defaults.

digits

Integer indicating the number of decimal places (round) or significant digits (signif) to be used.

main

main title

. . .

Arguments to be passed to methods.

PPO 25

#### Value

OOB error and test error of newdata, misclassification rate (MR) for classification or mean square error (MSE) for regression.

#### See Also

```
ODT plot.ODT
```

#### **Examples**

```
data(body_fat)
set.seed(221212)
train <- sample(1:252, 100)
train_data <- data.frame(body_fat[train, ])
test_data <- data.frame(body_fat[-train, ])
plot_ODT_depth(Density ~ ., train_data, test_data, type = "regression")</pre>
```

PP0

Projection Pursuit Optimization

#### **Description**

Find the optimal projection using various projectin pursuit models.

#### Usage

```
PPO(X, y, model = "PPR", type = "i-classification", weights = NULL, ...)
```

#### **Arguments**

model

X An n by d numeric matrix (preferable) or data frame.

y A response vector of length n.

Model for projection pursuit."PPR"(default): projection projection regression from ppr. When y is a

category label, it is expanded to K binary features.

- "Log": logistic based on nnet.
- "Rand": The random projection generated from  $\{-1,1\}$ . The following models can only be used for classification, i.e. the type must be 'i-classification' or 'g-classification'.
- "LDA", "PDA", "Lr", "GINI", and "ENTROPY" from library PPtreeViz.
- The following models based on Pursuit.
  - "holes": Holes index
  - "cm": Central Mass index
  - "holes": Holes index
  - "friedmantukey": Friedman Tukey index
  - "legendre": Legendre index
  - "laguerrefourier": Laguerre Fourier index
  - "hermite": Hermite index,

26 PPO

- "naturalhermite": Natural Hermite index

- "kurtosismax": Maximum kurtosis index,

- "kurtosismin": Minimum kurtosis index,

- "moment": Moment index

- "mf": MF index

- "chi": Chi-square index

type The criterion used for splitting the variable. 'g-classification': gini impurity

index (classification, default), 'i-classification': information gain (classification)

or 'regression': mean square error (regression).

weights Vector of non-negative observational weights; fractional weights are allowed

(default NULL).

optional parameters to be passed to the low level function.

#### Value

Optimal projection direction.

predict.ODRF 27

predict based on ODRF objects	redict.ODRF
-------------------------------	-------------

## **Description**

Prediction of ODRF for an input matrix or data frame.

#### Usage

```
## S3 method for class 'ODRF'
predict(object, Xnew, type = "response", weight.tree = FALSE, ...)
```

## **Arguments**

object	An object of class ODRF, as that created by the function ODRF.
Xnew	An n by d numeric matrix (preferable) or data frame. The rows correspond to observations and columns correspond to features.
type	One of response, prob or tree, indicating the type of output: predicted values, matrix of class probabilities or predicted value for each tree.
weight.tree	Whether to weight the tree, if TRUE then use the out-of-bag error of the tree as the weight. (default FALSE)
	Arguments to be passed to methods.

#### Value

A set of vectors in the following list:

- response: the prediced values of the new data.
- prob: matrix of class probabilities (one column for each class and one row for each input). If ppForest\$type is regression, a vector of tree weights is returned.
- tree: it is a matrix where each column contains prediction by a tree in the forest.

predict.ODT

predict method for ODT objects

#### **Description**

Prediction of ODT for an input matrix or data frame.

## Usage

```
## S3 method for class 'ODT'
predict(object, Xnew, leafnode = FALSE, ...)
```

## **Arguments**

object An object of class ODT, as that created by the function ODT.

Xnew An n by d numeric matrix (preferable) or data frame. The rows correspond to

observations and columns correspond to features.

leafnode If or not output the leaf node sequence number that Xnew is partitioned. (default

FALSE)

... Arguments to be passed to methods.

#### Value

A vector of the following:

- prediction: the prediced response of the new data.
- leafnode: the leaf node sequence number that the new data is partitioned.

prune

prune ODT or ODRF

## **Description**

Prune ODT or ODRF from bottom to top with validation data based on prediction error, and prune is a S3 method for class ODT and ODRF.

#### Usage

```
prune(obj, ...)
```

prune.ODRF 31

#### **Arguments**

objAn object of class ODT or ODRF....For other parameters related to class obj, see ODT or ODRF.

#### Value

An object of class ODT and prune.ODT.

#### See Also

```
ODT ODRF prune.ODT prune.ODRF
```

prune.ODRF

Pruning of class ODRF.

## **Description**

Prune ODRF from bottom to top with test data based on prediction error.

## Usage

```
## S3 method for class 'ODRF'
prune(obj, X, y, MaxDepth = 1, useOOB = TRUE, ...)
```

## **Arguments**

obj An object of class ODRF.

X An n by d numeric matrix (preferable) or data frame is used to prune the object

of class ODRF.

y A response vector of length n.

MaxDepth The maximum depth of the tree after pruning (Default 1).

use00B Whether to use OOB for pruning (Default TRUE). Note that when use00B=TRUE,

X and y must be the training data in ODRF.

... Optional parameters to be passed to the low level function.

#### Value

An object of class ODRF and prune. ODRF.

ppForest The same result as ODRF.

• pruneError Error of test data or OOB after each pruning in each tree, misclassification rate (MR) for classification or mean square error (MSE) for regression.

```

RotMatMake

Create rotation matrix used to determine linear combination of features.

## Description

Create any projection matrix with a self-defined projection matrix function and projection optimization model function

34 RotMatMake

#### **Usage**

```
RotMatMake(
  X = NULL
  y = NULL,
  RotMatFun = "RotMatPPO",
  PPFun = "PPO",
  FunDir = getwd(),
  paramList = NULL,
)
```

## **Arguments** Χ

A response vector of length n. У A self-defined projection matrix function name, which can also be RotMatRand RotMatFun and RotMatPPO. Note that (, . . .) is necessary. **PPFun** A self-defined projection matrix function, which can also be PPO. Note that  $(, \dots)$  is necessary. FunDir The path to the function of the user-defined NodeRotateFun. (default current

An n by d numeric matrix (preferable) or data frame.

Workspace)

List of parameters used by the functions RotMatFun and PPFun. If left unparamList

changed, default values will be used, for details see defaults.

Used to handle superfluous arguments passed in using paramList.

#### **Details**

There are two ways for the user to define a projection direction function. The first way is to define a function directly, and just let the argument RotMatFun be the name of the defined function and let the argument paramList be the arguments used in the defined function; the second way is to use the function RotMatMake following the way in the example below. Note that the name of the defined function cannot be the name of an existing function in the ODRF package

#### Value

A random matrix to use in running ODT.

• Variable: Variables to be projected.

• Number: Number of projections.

• Coefficient: Coefficients of the projection matrix.

#### See Also

)
```

RotMatPP0

Create a Projection Matrix: RotMatPPO

#### **Description**

Create a projection matrix using projection pursuit optimization (PP0).

36 **RotMatPPO** 

#### Usage

```
RotMatPPO(
                Χ,
                у,
                model = "PPR",
                type = "i-classification",
                weights = NULL,
                dimProj = min(ceiling(length(y)^0.4), ceiling(ncol(X) * 2/3)),
              numProj = ifelse(dimProj == "Rand", max(5, sample(floor(ncol(X)/3), 1)), max(5, sam
                                 ceiling(ncol(X)/dimProj))),
                catLabel = NULL,
)
```

## **Arguments**

X	An n by d numeric matrix (preferable) or data frame.
у	A response vector of length n.
model	Model for projection pursuit (for details see PPO).
type	The criterion used for splitting the variable. 'i-classification': information gain (classification, default), 'g-classification': gini impurity index (classification) or 'regression': mean square error (regression).
weights	A vector of length same as data that are positive weights. (default NULL)
dimProj	Number of variables to be projected, $dimProj=min(ceiling(n^0.4), ceiling(ncol(X)*2/3))$ (default) or $dimProj="Rand": random from 1 to ncol(X).$
numProj	The number of projection directions, when $\dim Proj="Rand"$ default $numProj=sample(ceiling(ncol(X)/3),1)$ otherwise default $numProj=ceiling(p0/dimProj)$ .
catLabel	A category labels of class 1ist in predictors. (default NULL, for details see Examples of ODT)
	Used to handle superfluous arguments passed in using paramList.

## Value

A random matrix to use in running ODT.

- Variable: Variables to be projected.
- Number: Number of projections.
- Coefficient: Coefficients of the projection matrix.

(PP <- RotMatPPO(body_fat[, 2:15], body_fat[, 1], model = "PPR", type = "regression"))</pre>
```

RotMatRand

Random Rotation Matrix

## **Description**

Generate rotation matrices by different distributions, and it comes from the library codererf.

#### Usage

```
RotMatRand(
   dimX,
   randDist = "Binary",
   numProj = ceiling(sqrt(dimX)),
   dimProj = "Rand",
   sparsity = ifelse(dimX >= 10, 3/dimX, 1/dimX),
   prob = 0.5,
   lambda = 1,
   catLabel = NULL,
   ...
)
```

#### **Arguments**

dimX	The number of dimensions.
randDist	The probability distribution of the random projection direction, including "Binary": $B\{-1,1\}$ binomial distribution (default), "Norm": $N(0,1)$ normal distribution, "Uniform": $U(-1,1)$ uniform distribution.
numProj	The number of projection directions (default ceiling(sqrt(dimX))).
dimProj	Number of variables to be projected, default dimProj="Rand": random from 1 to dimX.
sparsity	A real number in $(0,1)$ that specifies the distribution of non-zero elements in the random matrix. When sparsity="pois" means that non-zero elements are generated by the p(lambda) Poisson distribution.
prob	A probability in $(0,1)$ used for sampling from $-1,1$ where prob = 0 will only sample -1 and prob = 1 will only sample 1.
lambda	Parameter of the Poisson distribution (default 1).

38 RotMatRF

CatLabel A category labels of class list in predictors. (default NULL, for details see Examples of ODT)
 Used to handle superfluous arguments passed in using paramList.

#### Value

A random matrix to use in running ODT.

- Variable: Variables to be projected.
- Number: Number of projections.
- Coefficient: Coefficients of the projection matrix.

(RotMat <- do.call(RotMatRand, paramList))</pre>
```

RotMatRF

Create a Projection Matrix: Random Forest (RF)

## Description

Create a projection matrix with coefficient 1 such that the ODRF (ODT) has the same partition variables as the random forest (tree).

## Usage

```
RotMatRF(dimX, numProj, catLabel = NULL, ...)
```

## **Arguments**

dimX	The number of dimensions.	
numProj	The number of projection directions (default ceiling(sqrt(dimX))).	
catLabel	A category labels of class list in predictors. (default NULL, for details see Examples of $\ensuremath{ODT}\xspace$ )	
	Used to handle superfluous arguments passed in using paramList.	

seeds 39

```

seeds

seeds Data Set

## **Description**

Measurements of geometrical properties of kernels belonging to three different varieties of wheat. A soft X-ray technique and GRAINS package were used to construct all seven, real-valued attributes.

#### Format

A data frame with 209 rows and 7 covariate variables and 1 response variable.

#### **Details**

The variables listed below, from left to right, are:

- area A
- perimeter P
- compactness  $C = 4*pi*A/P^2$
- · length of kernel
- · width of kernel
- · asymmetry coefficient
- · length of kernel groove
- varieties of wheat (1, 2, 3 for Kama, Rosa and Canadian respectively)

## **Examples**

```
data(seeds)
set.seed(221212)
train <- sample(1:209, 100)
train_data <- data.frame(seeds[train, ])
test_data <- data.frame(seeds[-train, ])

forest <- ODRF(varieties_of_wheat ~ ., train_data,
    type = "i-classification", parallel = FALSE
)
pred <- predict(forest, test_data[, -8])
# classification error
(mean(pred != test_data[, 8]))

tree <- ODT(varieties_of_wheat ~ ., train_data, type = "i-classification")
pred <- predict(tree, test_data[, -8])
# classification error
(mean(pred != test_data[, 8]))</pre>
```

VarImp

variable importance of oblique decision random forest

## **Description**

Variable importance is computed from permuting OOB data.

#### Usage

```
VarImp(ppForest, X, y)
```

#### **Arguments**

```
ppForest An object of class ODRF.

X An n by d numerical matrix (preferably) or data frame is used in the ODRF.

y A response vector of length n is used in the ODRF.
```

#### **Details**

A note from randomForest package, here are the definitions of the variable importance measures. The measure is computed from permuting OOB data: For each tree, the prediction error on the out-of-bag portion of the data is recorded. Then the same is done after permuting each predictor variable. The difference between the two are then averaged over all trees.

VarImp 41

## Value

A matrix of importance measure, first column is the predictors and second column is Increased error. Misclassification rate (MR) for classification or mean square error (MSE) for regression.
